Climate inequality

This article documents a new fact—that transitory temperature shocks tend to increase within-country income inequality substantially and persistently—and considers its implications for the welfare economics of climate change. First, I use grouped income data from distributional national accounts to estimate dynamic growth incidence responses to an identified pulse of temperature over a multidecadal projection horizon. This is accomplished by refining recently developed time series methods to flexibly address several statistical concerns raised in recent literature with minimally restrictive parametric assumptions. Results depict non-linear income gradients funnelling marginal costs to lower-income groups and concentrating marginal relative benefits in narrow high-income quantiles. This pattern of relative incidence is found to be surprisingly consistent across geographies while still reproducing the stark temperature-based aggregate divergence consistently recovered in abundant empirical work. Reconciling the results entails rejecting intuitive and commonly offered bottom-up explanations for the aggregate divergence, demonstrating the value in departing from distribution-agnostic utilitarian approaches standard in the economic literature.

I then integrate this dynamic impulse response model with the outputs of a suite of climate models to simulate the influence of anthropogenic climate change on the global income distribution first i) between 1960-2016 and then ii) under a variety of climate forcing scenarios projected through to 2100. I integrate the results from this counterfactual exercise with a stylized model incorporating a variety of alternative social welfare functions from which welfare-maximizing fiscal policy can be derived. I close by relating these findings to the cost-benefit paradigm in the economics of climate change and consideration of redistributive climate policy.

Large potential reduction in economic damages under UN mitigation targets

with Marshall Burke, Noah S. Diffenbaugh — *Nature* (2018)

We present a probabilistic framework for assessing aggregate economic impacts of anthropogenic warming. Our construction decomposes uncertainty associated with mid-century and end-of-century GDP projections into error associated with i) econometric estimation of the economic effects of environmental change, ii) climate models of the spatial distribution of anthropogenic warming, iii) the projected schedule of greenhouse gas concentrations associated with radiative forcings, and iv) the social discounting regime of choice. We apply this framework to characterize the economic benefits of climate policy, emphasizing how achieving the most ambitious mitigation targets of the 2015 Paris Agreement would obviate essentially certain economic calamity concentrated in developing countries.

Combining satellite imagery and machine learning to predict poverty

with Neal Jean, Marshall Burke, Michael Xie, David B. Lobell, Stefano Ermon — *Science* (2016)

We demonstrate a scalable method to address the scarcity and prohibitive expense of collecting disaggregated welfare data in the developing world by extracting economic information from an unconventional but abundant data source with increasingly frequent and near-global coverage: daytime satellite photography. Our "transfer learning" pipeline proceeds by first assigning a convolutional neural network model pre-trained for generic image classification the task of identifying features in georeferenced satellite images predictive of night-time luminosity, a crude proxy for economic activity. In effect, the CNN learns to produce a nonlinear mapping from high-resolution unstructured image data to low-dimensional vector representations of their most economically relevant features. Ridge regression models are then trained on survey data to refine the feature selection for out-of-sample predictive performance. In an exploratory application to five diverse sub-Saharan African countries—Nigeria, Tanzania, Uganda, Malawi, and Rwanda—our open-source models trained on publicly available data are found to explain up to 75% of the variation in village-level consumption and asset wealth measured by traditional household surveys.

Teaching

Graduate Teaching Fellow at Columbia University (nine semesters, 2020–2024)
Research consultant to all UG/MA economics thesis writers and research assistants
ECON-4999 – Senior honors thesis workshops (design and instruction)
ECON-3412 – Introduction to econometrics (TA)
ECON-3211 – Intermediate microeconomics (TA)
ECON-2257 – The global economy (TA)

Past affiliations

Research associate at Climate Econometrics (2017–2019)
Nuffield College, University of Oxford
supervised by David F. Hendry, Elizabeth Baldwin

Pre-doctoral scholar at Center on Food Security and the Environment (2015–2017)
Dept. of Earth System Science, Stanford University
supervised by Marshall Burke, David Lobell

Honors

Program for Economic Research Summer Fellowship (2024)
Columbia economics department award supporting summer research activities

Wueller Fourth-Year Pre-Dissertation Award (2023)
Columbia economics department runner-up best dissertation proposal

UC Berkeley and Sloan Foundation Diversity Fellowship (2022)
Awarded to five doctoral students in environmental and energy economics

Columbia GSAS Dean's Fellowship and Dissertation Fellowship (2019)
Full-tuition scholarship and living stipend for up to six years of graduate study at Columbia

Oxford M.Phil top-scoring economics thesis (2019)
Department's first 'exceptional' (mark of 80+) thesis in at least four years

Nuffield College–Department of Economics Joint Studentship (2017)
Full-tuition scholarship and living stipend for up to four years of graduate study at Oxford
